What is Solr cloud?

is a distributed search and analytics engine built on top of Apache Lucene. It is a search server that can be deployed on multiple servers. It has a central configuration, schema, and indexing management. It also has a distributed search and indexing system. It is used for search engines, document retrieval, and data mining.

What does Solr stand for?

Solr (Search On Lucene with Replication) is a free, open-source search engine. It is based on the Apache Lucene library. An Apache Lucene subproject, it has been developed by the Apache Software Foundation. It is one of the most popular search engines available today worldwide.

What are shards in Solr?

Shards are used to partition a collection into smaller units. This allows us to put one shard of a collection on each node. As the number of nodes we have increases, we can also increase the number of shards. We can also do this by using Configuration files.

What is Sharding in Solr?
